# Analysis of TCR:pMHC complexes having the same antigen but distinct CDR3beta

Mikhail Ignatov, Mikhail Shugay July 30, 2016

This analysis shows that while TCRs recognizing the same antigen can have highly dissimilar CDR3 sequences, their spatial patterns of CDR3:antigen interactions (namely, maps of pairwise amino acid distances) observed in structural data are extremely similar.

Start with loading our master table.

```
df <- read.table("../result/structure.txt", header=T, sep="\t")</pre>
```

Select complexes for further analysis. We select complexes that have at least 2 distinct CDR3 beta with the same antigen and no duplicate CDR3 beta.

Next, we will draw contact maps, i.e. heatmaps of pairwise distances between CDR3beta and antigen residues as computed from structural data. We will also provide multiple alignments of CDR3beta sequences associated with a given antigen after each plot.

Next compute distances by aligning and computing distance matrix RMSD. While the matrices above look similar within CDR3beta subset recognizing the same antigen and different between different antigens, it is well known that computing similarity between two heatmaps is a complex task (see SO thread and this paper). So, instead of implementing all those complex stats here we'll simply compute RMSD between matrices:

- We will allow -5:5 offset for the CDR3 dimension (antigen dimension/columns are fixed)
- We will select the best distance among those offsets
- We will compute RMSD for 1/distance to give more weight for closer residues we are really interested in

Note: we can use exp(-distance) to get the same result & matrices will be very similar to energy matrices, we can also get similar results with energy matrices. But for consistency (the MS is based on distances and <=6A threshold) we'll stick to distances here.

Some helper functions to align/compute distance between contact matrices.

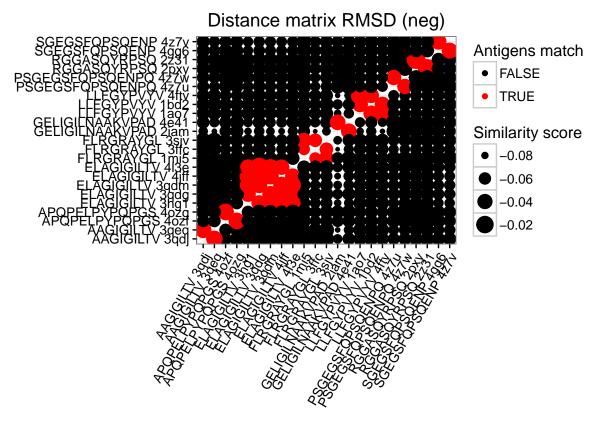

```
library(Biostrings)
# Global pairwise alignment with default parameters
```

```
get_full_seq <- function(tcr_data) {</pre>
  as.character(tcr_data$tcr_region_seq[1])
}
get_aln_score <- function(tcr_data1, tcr_data2) {</pre>
  pairwiseAlignment(get_full_seq(tcr_data1), get_full_seq(tcr_data2), scoreOnly = T)
# Computing RMSD between inverted AA pairwise distance matrices
get_pos_dist_mat <- function(tcr_data, offset = 0) {</pre>
  data.frame(pos_tcr = tcr_data$pos_tcr + offset,
              pos_antigen = tcr_data$pos_antigen,
              distance = tcr_data$distance)
}
get_matrix_score <- function(tcr_data1, tcr_data2, offset_range = 5) {</pre>
  dmin <- 99999
  for (offset in -offset_range:offset_range) {
    d1 <- get_pos_dist_mat(tcr_data1, offset)</pre>
    d2 <- get_pos_dist_mat(tcr_data2)</pre>
    dd <- merge(d1, d2, by = c("pos_tcr", "pos_antigen"))</pre>
    dmin <- min(dist(rbind(1/dd$distance.x, 1/dd$distance.y))[1] / sqrt(nrow(dd)),</pre>
                 dmin)
  }
  -dmin
}
```

The computation itself (a bit time consuming, haven't optimized).

Plot similarity maps computed using CDR3 alignment and contact matrix correlation. Highlight TCR beta variants that recognize the same antigen.

# CDR3 alignment score SGEGSEGENE 4277 PSGEGSEGENE 4277 GELIGITATION 1007 GELIGITATION 1007 APOPEL PYROPES 4277 AAGIGILIV 3007 AAGIGILIV

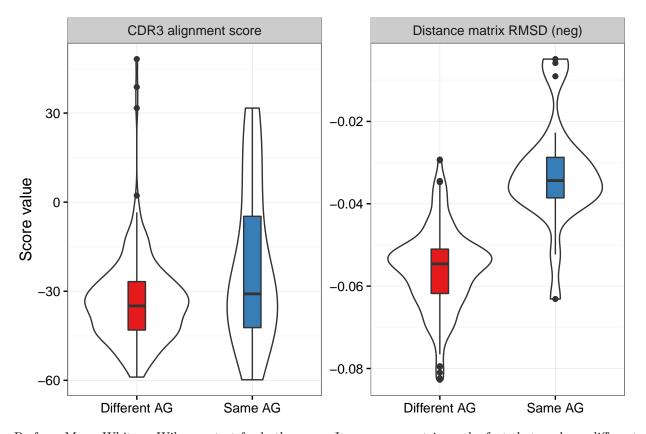

Its clear from the previous plot that CDR3 alignment scores cannot be used to match CDR3beta with the same antigen. On the other hand, RMSD values computed for CDR3:antigen distance matrices can distinguish complexes with the same antigen.

```
library(reshape2)
df.dd <- melt(df.d)</pre>
```

## Using pdb\_id\_2, pdb\_id\_1, antigen\_seq\_1, antigen\_seq\_2 as id variables

```
geom_violin() +
geom_boxplot(width=0.2, aes(fill=same_ag)) +
scale_fill_brewer(guide=F, palette = "Set1") +
facet_wrap(~variable, scales = "free") +
xlab("") + ylab("Score value") +
theme_bw()
```

Perform Mann-Whitney-Wilcoxon test for both scores. Its non-parametric so the fact that we have different scales/distributions for our scores is not a problem.

```
df.dda <- subset(df.dd, variable == "CDR3 alignment score")
df.ddr <- subset(df.dd, variable == "Distance matrix RMSD (neg)")
wilcox.test(value ~ same_ag, data=df.dda)

##
## Wilcoxon rank sum test with continuity correction
##
## data: value by same_ag
## W = 1959.5, p-value = 0.07647
## alternative hypothesis: true location shift is not equal to 0

wilcox.test(value ~ same_ag, data=df.ddr)

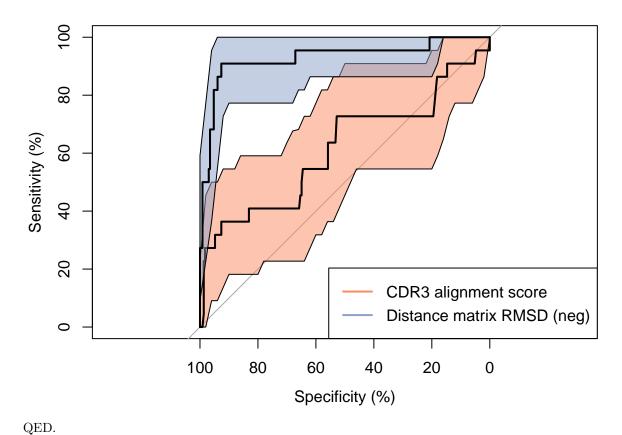

##
## Wilcoxon rank sum test with continuity correction
##
## Wilcoxon rank sum test with continuity correction
##</pre>
```

```
## data: value by same_ag
## W = 364, p-value = 3.22e-11
## alternative hypothesis: true location shift is not equal to 0
```

Finally, lets plot ROC curves for both scores.

```
library(pROC)
```

```
## Type 'citation("pROC")' for a citation.
##
## Attaching package: 'pROC'
## The following objects are masked from 'package: IRanges':
##
##
       cov, var
## The following objects are masked from 'package:stats':
##
##
       cov, smooth, var
rocobj1 <- plot.roc(df.dda$same_ag, df.dda$value, percent=T, col="#fc8d62", ci=T)</pre>
rocobj2 <- lines.roc(df.ddr$same_ag, df.ddr$value, percent=T, col="#8da0cb", ci=T)</pre>
sens.ci <- ci.se(rocobj1, specificities=seq(0, 100, 2))</pre>
plot(sens.ci, type="shape", col = alpha("#fc8d62", 0.5))
sens.ci <- ci.se(rocobj2, specificities=seq(0, 100, 2))</pre>
plot(sens.ci, type="shape", col = alpha("#8da0cb", 0.5))
legend("bottomright", legend=c("CDR3 alignment score", "Distance matrix RMSD (neg)"),
       col=c("#fc8d62", "#8da0cb"), lwd=2)
```

PS. There are similar figures for CDR3alpha chains in the analysis/sandbox/ folder of tcr-pmhc-study repo.
